# Consensus number: n-thread consensus problems

# Consensus number: n-thread consensus problems

$$1, 2, n, \cdots \infty$$

## Definition (Consensus Number)

The *consensus number* of a class C of synchronization primitive is the largest n for which C *solves*<sup>a</sup> n-thread consensus.

If no largest n exists, the consensus number is said to be *infinite*.

# The beautiful idea of "Consensus Numbers". (Maurice Herlihy@TOPLAS'1991)

# Wait-Free Synchronization

MAURICE HERLIHY
Digital Equipment Corporation

A wait-free implementation of a concurrent data object is one that guarantees that any process can complete any operation in a finite number of steps, regardless of the execution speeds of the other processes. The problem of constructing a wait-free implementation of one data object from another lies at the heart of much recent work in concurrent algorithms, concurrent data structures, and multiprocessor architectures. First, we introduce a simple and general technique, based on reduction to a consensus protocol, for proving statements of the form, "there is no wait-free implementation of X by Y." We derive a hierarchy of objects such that no object at one level has a wait-free implementation in terms of objects at lower levels. In particular, we show that atomic read/write registers, which have been the focus of much recent attention, are at the bottom of the hierarchy: they cannot be used to construct wait-free implementations of many simple and familiar data types. Moreover, classical synchronization primitives such as test&est and fetch&add. while more powerful than read and write, are also computationally weak, as are the standard message-passing primitives. Second, nevertheless, we show that there do exist simple universal objects from which one can construct a wait-free implementation of any sequential object.

# Theorem (Consensus Numbers)

Consensus Number	Object
1	read/write registers
2	test&set, swap, fetch&add, queue, stack
:	:
2n-2	n-register assignment
:	:
∞	memory-to-memory move and swap, augmented queue, compare&swap, fetch&cons, sticky byte

## Theorem (Consensus Numbers)

Consensus Number	Object

# **Decide**

# Propose

#### **Decide**

Definition (The Consensus Problem)

Consistent All (non-faulty) threads must agree on the same value.

Validity The common decision value must be the value *proposed* by some thread.

Wait-free Each (non-faulty) thread must decide in a *finite* number of steps.

#### On the Nature of Progress

# Consensus Protocol

## Definition (Consensus Protocol (Informally))

A *consensus protocol* is a system of n *threads* that communicate through a set of *shared objects*.

Propose

$$\{0,1\}^n$$

Communicate

invocation response

Decide

$$\{0,1\}^n$$

#### Definition (Consensus Protocol (Informally))

A *consensus protocol* is a system of n *threads* that communicate through a set of *shared objects*.

Propose

$$\{0,1\}^n$$

Communicate

invocation response

Decide

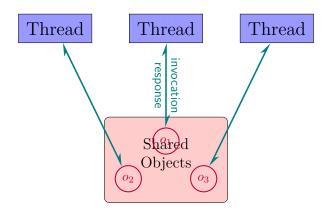

$$\{0,1\}^n$$

It *correctly* solves the n-thread consensus problem:

Consistent · · ·

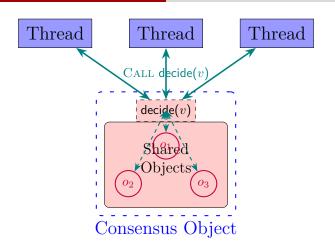

Valid · · ·

Wait-free · · ·

Threads communicate through shared objects.

20 / 48

```
interface Consensus {
   int decide(int val);
}
```

## Definition ("Solves")

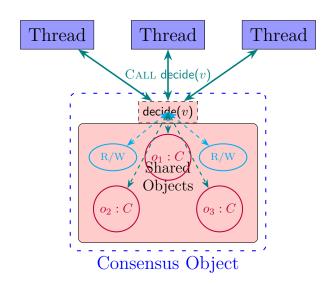

A *class* C of synchronization primitive *solves* n-thread consensus if there exist a *consensus protocol* using

- (i) any number of objects of class C
- (ii) any number of atomic read/write registers

## Definition ("Solves")

A  $class\ C$  of synchronization primitive  $solves\ n$ -thread consensus if there exist a  $consensus\ protocol$  using

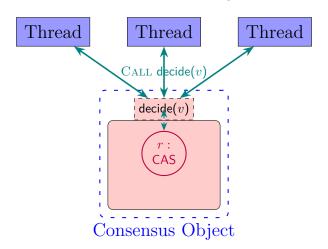

- (i) any number of objects of class C
- (ii) any number of atomic read/write registers
- (iii) initialized to any state

A class C solves n-thread consensus.

# n-Consensus Protocol Using (a Single) CAS

```
class CASConsensus implements Consensus {
 // shared CAS object
  CAS r = new CAS(\perp); // initialized
  int decide(int val) {
    first = r.compareAndSet(⊥, val);
    if (first == \bot)
      return val; // I won
    else
      return first; // I lose
```

```
class CASConsensus implements Consensus {
 // shared CAS object
 CAS r = new CAS(\perp); // initialized
  int decide(int val) {
    first = r.compareAndSet(⊥, val);
    if (first == \bot)
      return val; // I won
    else
      return first; // I lose
```

The decision value is established by the thread that *succeeds*.

### Theorem (Power of CAS)

A CAS register providing the compareAndSet() method can solve the consensus problem for any number of threads.

### Theorem (Power of CAS)

A CAS register providing the compareAndSet() method can solve the consensus problem for any number of threads.

### Theorem (Power of CAS)

A CAS register providing the compareAndSet() method has the consensus number  $\infty$ .

Theorem (Consensus Number of Atomic Registers)

Atomic read/write registers have consensus number 1.

### Theorem (Consensus Number of Atomic Registers)

Atomic read/write registers have consensus number 1.

Theorem ("Weakness" of Atomic Registers)

Atomic read/write registers cannot solve 2-thread consensus.

By contradiction

 $\exists \mathcal{P} \text{ solves } 2\text{-thread consensus}$

Every n-thread consensus protocol has a bivalent initial state.

Every n-thread consensus protocol has a bivalent initial state.

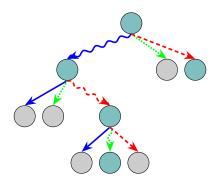

Theorem (Existence of Critical States)

Every wait-free consensus protocol has a critical state.

Every n-thread consensus protocol has a bivalent initial state.

### Theorem (Existence of Critical States)

Every wait-free consensus protocol has a critical state.

Atomic read/write registers cannot solve 2-thread consensus.

Atomic read/write registers cannot solve 2-thread consensus.

Proof.

(i) By contradiction:  $\exists \mathcal{P}$ 

Atomic read/write registers cannot solve 2-thread consensus.

### Proof.

- (i) By contradiction:  $\exists \mathcal{P}$
- (ii) Run  $\mathcal{P}$  until it reaches a critical state s.

Atomic read/write registers cannot solve 2-thread consensus.

### Proof.

- (i) By contradiction:  $\exists \mathcal{P}$
- (ii) Run  $\mathcal{P}$  until it reaches a critical state s.

Q: What are the next decision steps of two threads?

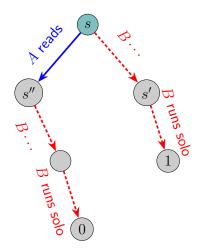

From the critical state s:

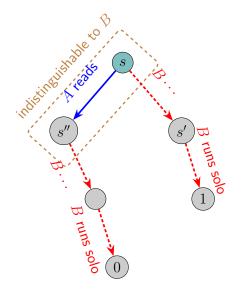

Case 1 A reads

Case 2 A writes  $r_0$ ; B writes  $r_1$ 

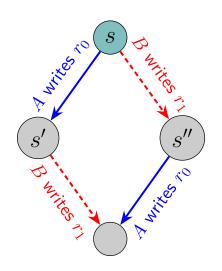

CASE 3 A writes r; B writes r

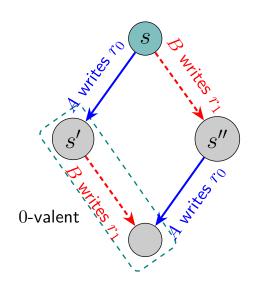

Case 1:  $A \text{ reads}_{\square \square \square \square \square}$ 

Case 1: A reads

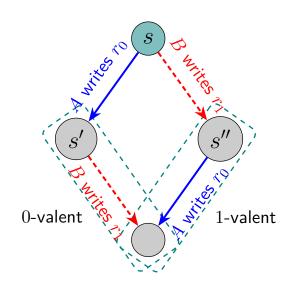

Case 2: A writes  $r_0$ ; B writes  $r_1$ 

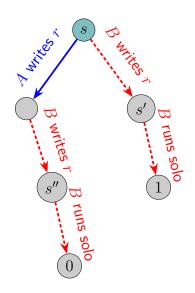

CASE 2: A writes  $r_0$ ;

B writes  $r_1$ 

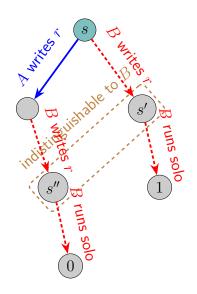

Case 2: A writes  $r_0$ ; B writes  $r_1$ 

40 / 48

CASE 3: A writes r;

B writes r

CASE 3: A writes r;

B writes r

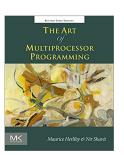

#### Theorem ("Weakness" of Atomic Registers)

It is impossible to construct a wait-free implementation of any object with consensus number  $\geq 2$  using atomic read/write registers.

#### Theorem ("Weakness" of Atomic Registers)

It is impossible to construct a wait-free implementation of any object with consensus number  $\geq 2$  using atomic read/write registers.

"... is perhaps one of the most striking impossibility results in Computer Science."

#### Theorem (Consensus Number 2)

The data types FIFO queue, stack, set, list, and priority queue all have consensus number 2.

#### Theorem (Consensus Number 2 (More))

The synchronization primitives get&set and get&add have consensus number 2.

### Impossibility of Distributed Consensus with One Faulty Process

MICHAEL J. FISCHER

Yale University, New Haven, Connecticut

NANCY A. LYNCH

Massachusetts Institute of Technology, Cambridge, Massachusetts

AND

MICHAEL S. PATERSON

University of Warwick, Coventry, England

Abstract. The consensus problem involves an asynchronous system of processes, some of which may be unreliable. The problem is for the reliable processes to agree on a binary value. In this paper, it is shown that every protocol for this problem has the possibility of nontermination, even with only one faulty process. By way of contrast, solutions are known for the synchronous case, the "Byzantine Generals" problem.
